

IT 630 · L09 · Try the matching-pair rule

Name: _____ Wed 9/30

Rule: a join makes one output row for every matching pair. Work from pairs, not intuition.

The company's trial: readings has two blood-pressure readings per participant. enrollment is the badge desk. It is clean except that **P02 appears twice** (P04 is back).

participant_id	systolic_bp
P01	130
P01	126
P02	138
P02	142
P03	124
P03	120
P04	108
P04	112

participant_id	arm
P01	drug
P02	placebo
P02	placebo
P03	drug
P04	placebo

Query: readings JOIN enrollment USING (participant_id)

1. Write the output rows for P02. Pair each reading with both enrollment records.

participant_id	systolic_bp	arm

2. Predict the results. Show your pairing work in the margin.

Total rows in the inner join:

Average systolic_bp of the placebo arm:

3. In one sentence: is the average wrong because of the query, or because of the rows it received?
